

Larger, eukaryotic cells, each with a nucleus, they have histones, introns and 80S ribosomes. Cell wall isn't always present (plants: cellulose, fungi: chitin).

EUKARYOTA

Animals Fungi Plants Eukaryotes

EUBACTERIA

Prokaryotes with no nucleus, histones or introns. They have 70S ribosomes and cell walls made of peptidoglycan.

Tiny, prokaryotes with no nucleus. Many are extremophile. They have proteins similar to histones, some introns and 70S ribosomes. Their cell walls are made of protein.

ARCHAEA

Sulfolobus Desulfurococcus Pyrodictium Thermoproteus Pyrobaculum Pyrococcus Methanothermus Methanopyrus Methanococcus Archaeoglobus other extremophiles

TAXONOMY

Organisms are all classified into three domains: archaea, Eubacteria and Eukaryota. The evidence for this is RNA sequences which evolve slowly in all organisms, therefore it is a study of the earliest evolutionary events.

Viruses are not classified by domains because they are not considered to be living organisms.

There are over 30 Phyla of animals. Recognition features of several large phyla are shown here:

Porifera: sponges

No clear symmetry. Attached to a surface. Pores through body. No mouth or anus.

Cnidaria: Jellyfish

Radially symmetric. Have tentacles and stinging cells. Mouth but no anus.

Platyhelminths: Flat worm

Bilaterally symmetric. Flat bodies. Unsegmented. Mouth but no anus.

Annelida: Earth worm

Bilaterally symmetric. Bristles often present. Segmented. Mouth and anus.

Arthropoda: Scorpions and spiders

Bilaterally symmetric. Have an exoskeleton. Segmented. Jointed appendages.

Mollusca: Snails

Muscular foot and mantle. Shell usually present. Segmentation not visible. Mouth and anus.

Chordata: Bony Fish

Notochord. Dorsal nerve cord. Pharyngeal gill slits. Post-anal tail.

Remember!

King Phillip Comes Over For Great Sex.

There are four main phyla of plants, they can be easily distinguished by studying their external structure:

Bryophytes (mosses)	Filicinophytes (ferns)
They have structures similar to root hairs called rhizoids—no roots.	They have roots, leaves and short non-woody stems.
Simple leaves and stems; e.g. liverworts have a flattened thallus.	Their leaves curl up in a bud and divide into leaflet pairs (pinnate).
No vascular tissue.	Vascular tissue present.
Spores are produced in a capsule; this capsule develops at the end of a stalk.	Spores produced in the sporangia on the underside of leaves.
Coniferophytes (conifers)	Angiospermophytes (flowering plants)
Shrubs or trees with roots, leaves and woody stems.	Usually have roots, leaves and stems.
Narrow leaves with thick waxy cuticle.	Stems of shrubs and trees are woody.
Vascular tissue present.	Vascular tissue present.
Seeds develop from ovules on the surface of the scales of female cones.	Seeds develop from ovules inside the ovaries of flowers.
Males cones produce pollen.	Fruit develops from ovaries to disperse the seeds.

Almost all chordates have a backbone consisting of vertebrae. Apart from fish, all these vertebrates are tetrapods with Pentadactyl limbs, though in some species the limbs have become modified or lost through evolution. Recognition features of the five major classes of vertebrate are shown here:

Bony ray-finned fish:

Scales grow from the skin. Gills with a single gill slit. Fins supported by rays. Swim bladder for buoyancy. External fertilisation.

Amphibians: Frogs

Soft moist permeable skin. Lungs with small internal folds. External fertilisation in water. Protective gel around eggs. Larval stage lives in water.

Reptiles: Lizards

Dry scaly impermeable skin. Lungs with extensive folding. Internal fertilisation. Soft shells around eggs. One type of teeth.

Birds: Blue Tit

Feathers growing from skin. Longs with parabronchial tubes. Wings instead of front legs. Hard shells around the eggs. Beak but no teeth.

Mammals: Elephants

Hairs growing from the skin. Lungs with alveoli. Give birth to live young. Mammary glands secrete milk. Teeth of different types.
